# HITA NV Uses SKUA-GOCAD to Generate State-of-the-art Structural Models for a Geothermal Project in Belgium

RESULTS

- Using SKUA-GOCAD software, HITA was able to integrate all existing data sets, convert the data from time to depth domain, and generate accurate depth structural models.

- The models provided the base for a thorough understanding of the reservoir's subsurface, which is an essential component in the safe and economical construction of geothermal plants.

## CUSTOMER
HITA NV

CHALLENGE
HITA NV is a young and ambitious Belgian company focused on the development of deep geothermal energy. Its goal is to contribute to energy transition by heating local homes and businesses using sustainable methods. Among its most important tasks is performing risk reduction for deep geothermal projects, ensuring that once constructed, the plants will be safe for both those working in them and the population at large.

In this case, there was a very deep geothermal project that needed to be de-risked in Northern Belgium. In projects such as these, geothermal heat is brought to the surface from a depth of 2-4 kilometers and distributed via a local network. In the early stages of the project, the company was looking for a suitable location for the production of geothermal heat (not electricity) for heating buildings. The reservoir lies in fractured carbonate limestones.

HITA geologists used all the available data, including old well and seismic as well as recently acquired 3D seismic data. Given the depth of the reservoir and its proximity to cities, it was critical to gain a thorough understanding of the subsurface in order to design a development plan for the safe and economic production of heat. Building a depth structural model was an essential step in this process.

> *"We are convinced of the added value of the SKUA-GOCAD software in reducing overall project risks by generating state-of-the-art subsurface models based on the integration of all available data sets."*

SOLUTION

The GOCAD Foundation Modeling and Structural Modeling modules in the SKUA-GOCAD software suite were selected as the most optimal data integrators, due to their ability to visualize both well and seismic data. The next major step was to perform seismic interpretations on vintage 2D seismic data sets as well as newly acquired 3D seismic data. Lastly, it was necessary to provide geological reports on the geothermal reservoirs, and create structural models. These structural models would be used in the creation of depth maps of the target reservoir that would act as input for well trajectory calculations.

The SKUA-GOCAD workflow included:

- Import of all available data: 2D and 3D seismic (various vintages) and well data (old data from coal mining industry)

- Velocity modeling, leveraging SKUA's advanced scripting capabilities

- Seismic interpretation, horizon mapping, seismic attribute extraction along surfaces, and structural modeling

- Identification of faulted structures to target, design of conceptual well trajectories (doublet)

- Export to third-party application for dynamic modeling

- Maps and views were used in the report submitted to regulatory authorities

RESULTS

Using the SKUA-GOCAD software, HITA was able to integrate all existing data sets, use velocity data to convert data sets from time to depth domain, and generate structural models. The models provided the base for a thorough understanding of the reservoir's subsurface, which is an essential component in the safe and economical construction of geothermal plants.

For a project in the city of Turnhout, a detailed 3D structural model was created of the target reservoir in the Lower Carboniferous Limestones. HITA is currently working on three locations for which 3D seismic acquisition was performed.

BENEFITS

Geothermal development companies often operate under budgetary restraints; however, HITA is convinced of the added value of the software in reducing overall project risks by generating state-of-the-art subsurface models based on all available data sets.

Due to a combination of the user-friendliness of the software and the increasing number of projects for which HITA has been contracted, the company recently extended its contract with Emerson E&P Software for the SKUA-GOCAD suite.
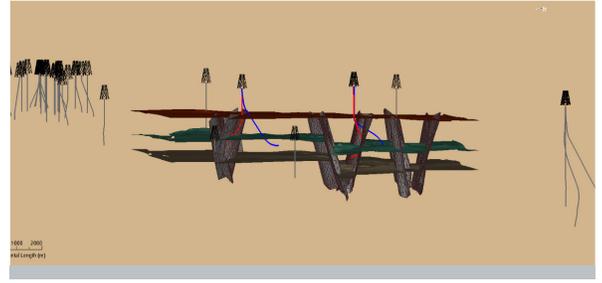

▲ *Once the 3D reservoir structural model is ready, it is used to support the design of conceptual well trajectories (doublet). It is also exported and used as input for dynamic geothermal simulation.*
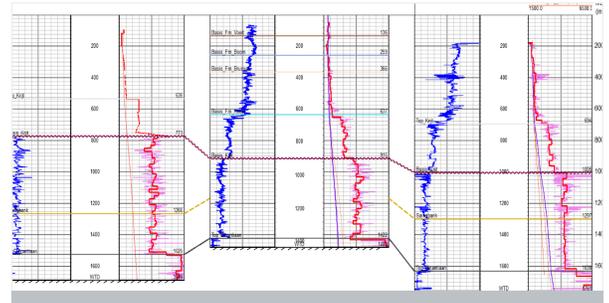

▲ *Well velocity logs and marker correlation used as input for velocity modeling in GOCAD.*
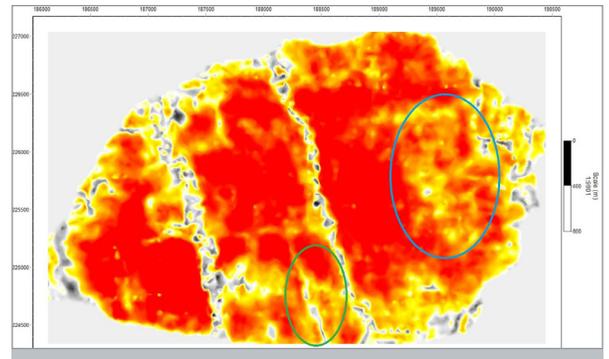

▲ *A seismic amplitude extraction along a mapped top reservoir surface indicating zones with (possibly) higher permeabilities*
